

1. We first show that  $E = (A \vee B D^* C)^*$ .

Let  $m$  be the number of rows of  $A$  and let

$V_1$  be the vertices corresponding to the first  $m$  rows.

Let  $V_2 = V \setminus V_1$ .

Define  $G_1 = (V_1, E_1)$  where  $e = uv \in E_1$  if  $(u, v \in V_1)$  either  $uv$  ~~is an edge in  $G$~~  or there exists a  $uv$ -path in  $G$  where all internal vertices are in  $V_2$ .

Then clearly  ~~$uv \in E_1$~~   $v$  is reachable from  $u$  in  $G$  iff  $v$  is reachable from  $u$  in  $G_1$ .

So it suffices to show that the adjacency matrix  $W_1$  of  $G_1$  is equal to  $A \vee B D^* C$ .

Indeed,  $A$  corresponds to the edges in  $G$  and, for  $u, v \in V_1$ ,

there is a  $uv$ -path in  $G$  with all internal vertices in  $V_2$  iff

$$e_u^T B D^* C e_v = 1, \text{ where } e_v \text{ is } (0, 0, \dots, 0, \underset{\substack{\uparrow \\ \text{v-coordinate}}}{1}, 0, \dots)$$

since  $e_u^T B$ ,  $C e_v$  have 1's only on edges on  $u, v$  with neighbors in  $V_2$ , and so  $(e_u^T B) D^* (C e_v)$  indicates the reachability in  $V_2$  of the neighbors of  $u, v$  in  $V_2$ .

Therefore  $E = (A \vee B D^* C)^*$ .

Similarly, for  $u \in V_2$  and  $v \in V_1$ , there is a  $uv$ -path in  $G$  iff for some edge  $e = ab \in G$ , ~~there is a~~,  $a \in V_2$ ,  $b \in V_1$ , there is a  $V_2$ -path from  $u$  to  $a$  and a  $V_1$ -path from  $b$  to  $v$ . Therefore  $G = D^* C E$ .

~~Same~~ Same argument with  $V_1, V_2$  ~~switched~~ switched gives  $F = E B D^*$ .

To show  $H = D^* v G B D^*$ , note that for  $u, v \in V_2$ , there is a  $uv$ -path in  $G$  iff either there is a  $uv$ -path in  $V_2$  (corresponding to  $D^*$ ) or there exists an edge  $e = ab$  such that  $a \in V_1$ ,  $b \in V_2$ , and:

- There is a  $ua$ -path in  $G$  (corresponds to the matrix  $G$ )
- $ab$  is an edge in  $G$  (  $\dots \dots \dots B$  )
- There is a  $bv$ -path in  $V_2$  (  $\dots \dots \dots D^*$  )

Therefore  $H = D^* v G B D^*$ ,

and this completes the proof of this part.

2.  $E = (A \vee BD^*C)^*$  : For  $u, v \in V_1$ , every  $uv$ -path is ~~either contained in  $V_1$  or~~ a concatenation of paths with internal edges in  $V_2$  and edges in  $V_1$ . Concatenation of paths is denoted by products of matrices, which sums the weights. The  $\vee$  operation takes the minimum of the two kinds of paths, so  $E = (A \vee BD^*C)^*$ .

For  $u \in V_2, v \in V_1$ , every  $uv$ -path ~~can be decomposed as before,~~  
~~with  $D^*$  giving shortest paths within  $V_2$  and  $E$  giving~~  
 shortest ~~paths~~ paths between two vertices of  $V_1$  in  $G$ .  
 The product  $D^*CE$  finds all valid concatenations and gives the minimum. Thus  $G = D^*CE$ .

Same argument gives  $F = EBD^*$

$H$  gives shortest paths between two vertices of  $V_2$  in  $G$ , which ~~is~~ is the min. of paths contained in  $V_2$  and paths that use  $V_1$ , so  $H = D^* \vee GBD^*$ .

3. Given a graph  $G$  on  $n$  vertices, we can compute APSP on  $G$  by ~~computing~~ dividing the vertices into two (near) equal sized parts, then applying the previous ideas to compute  $W^*$ .

This requires computing:

- $D^*$  — takes  $\text{APSP}(n/2)$  time
- $(A \vee BD^*C)^*$  — ~~2~~  $2 \cdot \text{MSP}(n/2) + O(n^2) + \text{APSP}(n/2)$
- $D^*CE$  —  $2 \text{MSP}(n/2)$
- $EBD^*$  —  $2 \text{MSP}(n/2)$
- $D^* \vee GBD^*$  —  $2 \text{MSP}(n/2) + O(n^2)$ .

Ⓢ

Note that  $(BD^*)$  ~~but~~ occurs 3 times, so we can skip two  $\text{MSP}(n/2)$  operations.

Ⓢ This gives a total of  $2 \cdot \text{APSP}(n/2) + 6 \text{MSP}(n/2) + O(n^2)$  running time.

Computing APSP recursively in this manner,  
noting that  $\text{APSP}(1)$  can be computed in constant time,  
we get:

$$\begin{aligned}
 \text{APSP}(n) &= 2 \text{APSP}(n/2) + 6 \text{MSP}(n/2) + O(n^2) \\
 &= 4 \text{APSP}(n/4) + 6 \text{MSP}(n/2) + 12 \text{MSP}(n/4) + O(n^2) + 2O((n/2)^2) \\
 &\vdots \\
 &= \sum_{k=1}^{\log n} 2^k O(1) + 6 \cdot 2^{k-1} \text{MSP}(n/2^k) + 2^{k-1} O((n/2^{k-1})^2) \\
 &= O(n) + 6 \sum_{k=1}^{\log n} 2^{k-1} \text{MSP}(n/2^k) + O(n^2) \underbrace{\sum_{k=1}^{\log n} O(1/2^{k-1})}_{\leq O(1)} \\
 &= 6 \sum_{k=1}^{\log n} 2^{k-1} \text{MSP}(n/2^k) + O(n^2)
 \end{aligned}$$

Since MSP is superlinear, it follows that

$$\text{APSP}(n) = \tilde{O}(\text{MSP}(n) + n^2)$$
